High-Level Overview

- SmartSat Cooperative Research Centre project
- Focussed on detecting satellite manoeuvres and anomalies using Two-Line-Element data (TLEs)
- Investigated different techniques:
 - Baseline
 - Particle Filters
 - Transformer Neural Networks
- Developed a chat interface
- Presented as a web app

Star

Motivation

- Growing need for Space Situational Awareness (SSA)
 - Knowledge of the orbits of satellites allows for mission planning, resource management and strategic countermeasures.
- Our subproblem: detect
 - manoeuvres (even station keeping) for large constellations
 - unexpected (anomalous) behaviour
 - failures, collisions, ...
 - patterns of behaviour

Need for SSA of increasing importance given the growing number of space objects and the growing technological importance of satellites

Number of space objects regularly tracked by Space Surveillance Networks $\simeq 42,000$

Estimated number of break-ups, explosions, collisions, or anomalous events > 650

Challenges

- Scale
 - 10s of thousands of objects
 - time-scale of years
- Data
 - We need ground truth to train and test
- Communicating results
 - Are dashboards enough?
- **Trust**
 - AI systems have a bad rep for promising everything, but failing in delivery

Star

Trusted AI

Factors that lead to trust

- Explainability
 - Interpretability
 - Transparency
- Benchmarking
 - Accuracy (known if not perfect)
 - Robustness (generalizability, out of distribution, new behaviour)
- User experience
 - Reliability
 - Safety
 - Balance between FA and FD

Anomaly detection usually falls down on benchmarking (lack of data) and user experience, but even explainability is getting worse these days with a proliferation of black-boxes.

Two-Line Element Data

TLEs

- Provided by the USA's 18th Space Defence Squadron
- Contains mean Keplerian orbital elements
- Updated roughly daily
- Comprehensive
- Low sample rate (roughly daily)

But TLEs aren't enough for training and testing – we need “ground” truth

Threshold choice

- Every technique returns an anomaly statistic (s_k) for each inspected epoch k .
 - Higher values are more indicative of an anomaly/manoeuvre
- Need to choose a threshold above which we predict a manoeuvre
- Try all possible thresholds
 - Each will have an associated precision and recall
 - Choose the tradeoff
 - Plot curve for testing
 - Note the idea of a “true negative” is a little fuzzy here because there isn't a 1:1 mapping from “non-event” to “non-detection”, so conventional ROC curves don't work, but we can do a precision-recall curve
- We can preserve the values to prioritise

Baseline Method

- Strawman from the literature
 - improved (see next slides)
- Propagate to the next epoch using SGP4
- Compare with the observed TLE at the next epoch
 - remember many orbits in 1 day
 - TLEs contain (unknown, non-Gaussian) noise
 - care needed between mean and osculating orbit

Particle Filters [3]

- Assume that the TLEs are noisy observations of true mean elements
- Filtering aims to find these true mean elements
 - along with an uncertainty
 - can be non-linear, non-Gaussian
- From our belief in one epoch, can find distribution of expected orbit in next epoch
 - track a swarm of particles
- If observation is sufficiently unlikely, according to this distribution, designate an anomaly

edu.au>

Introduction

Manoeuvre
Detection
Techniques

Manoeuvres of
Starlink
Satellites

Web App

Conclusion

Extra Slides

Track a swarm of particles each following:

$$\mathbf{x}_k = f_{\text{SGP4}}(\mathbf{x}_{k-1}, t_{k-1}, t_k) + \boldsymbol{\xi} \quad (1)$$

where $\boldsymbol{\xi} \sim \mathcal{N}(0, \mathbf{Q})$ and t_k is the epoch time associated with the k^{th} TLE. $\mathbf{x}_k$ is the vector of underlying mean orbital elements and we observe

$$\mathbf{y}_k = \mathbf{x}_k + \boldsymbol{\eta}_k \quad (2)$$

where $\boldsymbol{\eta}_k \sim \mathcal{N}(0, \mathbf{R})$

Uncertainty

- SGP4 has substantial errors in the argument of perigee and mean anomaly.
 - Although their sum is more accurate
- Much focus was therefore applied to finding appropriate uncertainty covariance matrices.
 - e.g. degenerate parameters

Transformers

- Train a neural network to perform reconstruction of windows of TLEs
- Lose information through initial dimensionality reduction
- Must use neighbouring epochs to reconstruct the TLE at a given epoch
- Through the attention mechanism we can track which TLEs are used
- Expect an interruption at manoeuvres

Manoeuvres of Starlink Satellites

Starlink Constellation [2]

So let's use the detector to look for patterns

- Around 5,000 satellites in StarLink (at the time of writing)
- 7 Orbital shells
 - Within shell: same altitude and inclination
- Each shell can be split into launch groups

Conclusion

Concluding Remarks

- Good detection of events
 - preference for particle filters
 - more explainable than transformers, but for some settings transformers are better
- Chat interface demonstrates a more general idea, but is still very much a prototype
- We are continuing this work
 - Funding news soon
 - Detection could be improved, but other topics are more urgent, e.g., working with other sources of data and event classification
 - Threshold determination in practice

```

Orbital Elements

They have weird names

- **Eccentricity:** how circular or elliptical ($0.0 - 1.0$)
- **Semi-major axis:** long axis of ellipse (half the distance between the apoapsis and periapsis) (
- **Inclination:** vertical tilt of the orbital plane with respect to the equator ($0.0 - 90.0$ degrees)
- **Longitude of the ascending node:** the direction the ellipse points.
- **Argument of periapsis:** rotation of ellipse around its plane relative to reference (perigee for Earth)
- **Mean motion:** average angular speed
- **Epoch:** time
- **Mean anomaly:** where we are on the orbit

TLEs use these, but there are alternative parameterisations.

F1 Score

F1 score is a way to combine precision and recall into one number

$$F_1 = \frac{2}{\text{recall}^{-1} + \text{precision}^{-1}} = 2 \frac{\text{precision} \cdot \text{recall}}{\text{precision} + \text{recall}} = \frac{2TP}{2TP + FP + FN}$$

With

$$\text{precision} = TP / (TP + FP)$$

$$\text{recall} = TP / (TP + FN)$$
